CYBERSECURITY PROJECT REPORT

15-Day Hands-On Project Submission

Project Title	Cybersecurity Help: Cybercrime Reporting Website for India
Student Name	Mohammed Eshaan
Batch / Cohort	Batch — 1 September 2026
Domain	Cybercrime Awareness & Incident Reporting
Trainer Name	Ganesh Kuche
Submission Date	28 / 10 / 2026
Difficulty Level	Beginner

SECTION 1 — PROJECT ABSTRACT

1. Project Abstract

Many victims of cybercrime in India do not know where to report it or whom to call, and valuable time is lost, especially in financial fraud. This project builds “Cybersecurity Help”, a single-page website that lists 20 types of cybercrime, such as phishing, SIM-swap fraud and ransomware, and shows the correct reporting route for each one. It links directly to the official National Cyber Crime Reporting Portal (cybercrime.gov.in) and CERT-In, and uses tap-to-call links for 1930, 112 and 181. The site includes search, filters and a language switcher for English, Hindi and Kannada. It was built with HTML, CSS and JavaScript, tested with VS Code Live Server, and gives users one clear place to start when something goes wrong online.

SECTION 2 — INTRODUCTION

2. Introduction

2.1 Background

Cybercrime covers offences such as phishing, online fraud, hacking, identity theft and blackmail carried out through computers and the internet. As more people use digital payments and social media, more people become victims. Quick reporting matters: for financial fraud, reporting to the national helpline 1930 as early as possible improves the chance of stopping the transaction. India provides official channels, including the National Cyber Crime Reporting Portal, the 1930 helpline, the 112 emergency number and CERT-In, but these are often unknown to ordinary users.

2.2 Problem Statement

Information about where to report each type of cybercrime is spread across several portals and phone numbers, mostly in English, and many victims do not know which route applies to them. The gap this project addresses is the lack of one simple, searchable, mobile-friendly guide that matches each cybercrime type to the correct official reporting route and lets the user call or open the portal in one tap.

2.3 Objectives

- To collect and organise official reporting information for 20 types of cybercrime in India.
- To build a responsive website with search and filters that matches each cybercrime type to its reporting route.
- To add one-tap links to the official government portal and tap-to-call links for 1930, 112 and 181.
- To make the site accessible to more people with English, Hindi and Kannada language options.
- To test the website locally using VS Code and Live Server and document the issues found.

3. Tools and Environment Setup

Tool / Software	Version / Platform	Purpose
Visual Studio Code	Current desktop version	Writing and editing the website code
Live Server extension (Ritwick Dey)	v5.7.10	Running a local server with live reload for testing
HTML, CSS and JavaScript	Web standards	Page structure, styling, search, filters and language switching
Web browser	Microsoft Edge / Chrome	Viewing and testing the website
Claude (Anthropic AI assistant)	Web (claude.ai)	Generating and refining the code and translations, which I reviewed
Official portals	cybercrime.gov.in, cert-in.org.in	Source of reporting routes and the destinations of the links

3.1 Lab / Environment Description

The project was developed on a Windows 11 laptop. The code is a single HTML file edited in Visual Studio Code and served locally by the Live Server extension at 127.0.0.1:5500. No virtual machine was needed. I opened the project folder in VS Code, trusted the workspace so the extension could run, and viewed the site in a web browser. A phone on the same Wi-Fi network was used to test tap-to-call.

4. Methodology

Step 1 — Collect and organise the reporting information

I started from a reference document listing the official cybercrime reporting websites, 20 cybercrime types, and the important contact numbers in India. I grouped the information into emergency numbers, the national portal, CERT-In, and one entry per cybercrime type with its reporting action.

```
1930 : financial cyber fraud helpline
112  : police emergency
181  : women's helpline
Portal: cybercrime.gov.in
CERT-In: cert-in.org.in
```

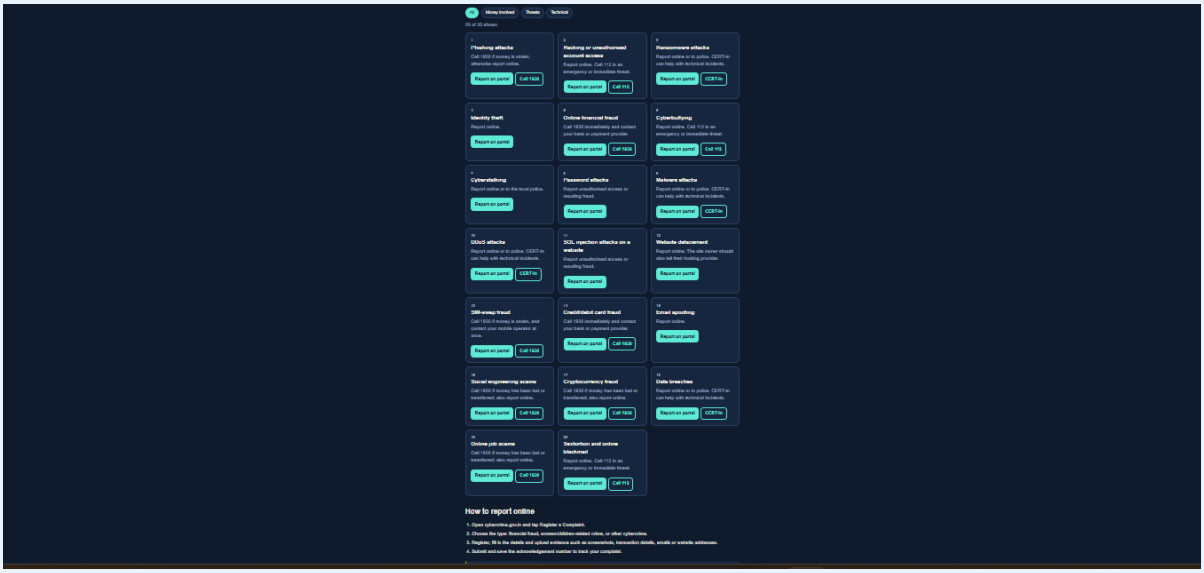

Figure 1: The source document of 20 cybercrime types and contact numbers.

Step 2 — Plan the structure and features

I planned a mobile-first single page with five parts: emergency number cards at the top, a searchable directory of cybercrime types, a guide on how to report online, a CERT-In section, and a short disclaimer. I decided that every card should offer an action, either the portal button or a call button.

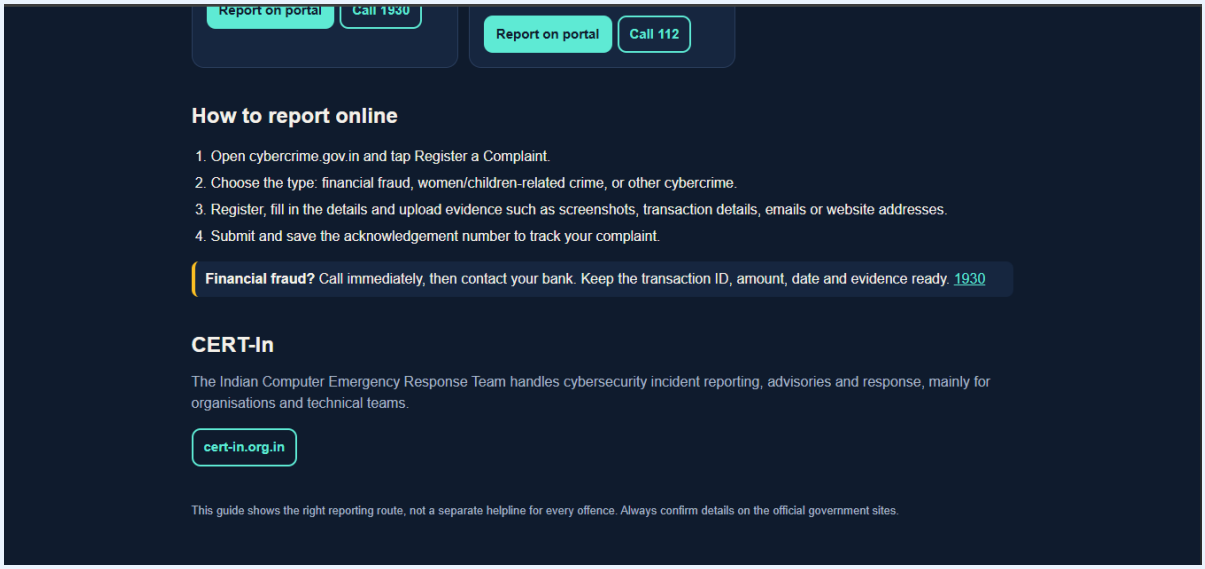

Figure 2: Sketch or outline of the website sections.

Step 3 — Build the page layout and styling

I wrote the HTML structure and CSS with a responsive grid so the cards fit both phones and laptops. I used colour variables so the page supports light and dark mode, and large tap-friendly buttons.

```
<a class="btn" href="tel:1930">Call 1930</a>
<div class="grid" id="list"></div>
```

Figure 3: Top of the website with the emergency number cards.

Step 4 — Add the directory with search and filters

I stored the 20 cybercrime types in a JavaScript array and rendered them as cards. A search box filters by name, and filter chips narrow the list to money-related crimes, threats or technical attacks. Each card shows its number, the recommended action and the relevant buttons.

```
var D=[["money",1],["tech",5],...];
// search box + filter chips call render()
```

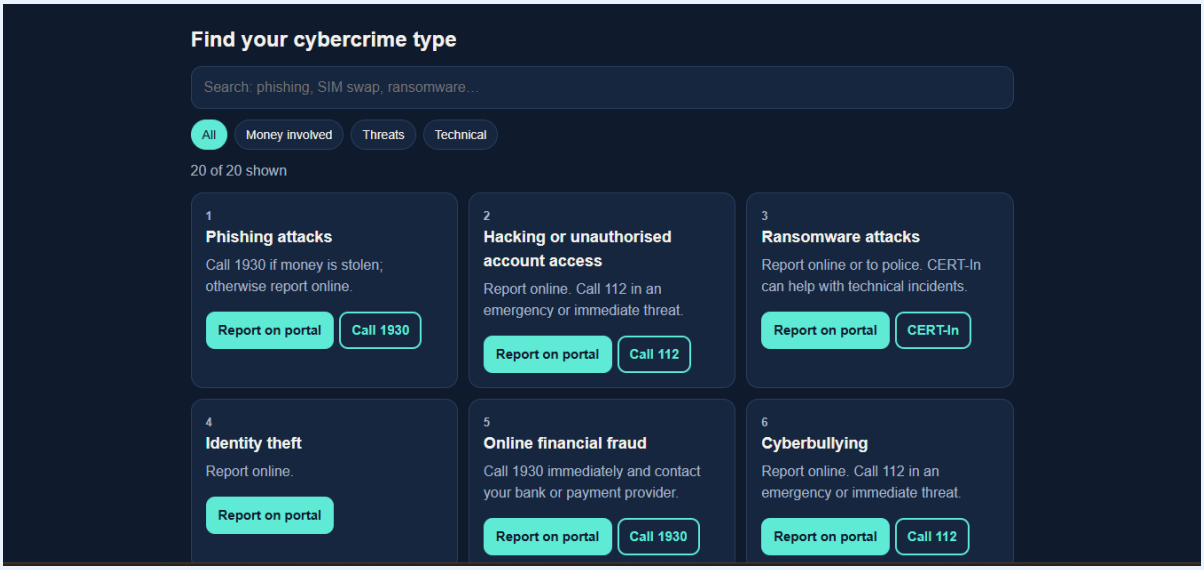

Figure 4: Directory of cybercrime types with search and filter chips.

Step 5 — Add official links and tap-to-call

Every card has a Report on portal button that opens https://cybercrime.gov.in/ in a new tab; I removed a tracking parameter from the original link. Phone numbers use tel: links so that a phone opens the dial pad with the number filled in. I also added a CERT-In link for technical incidents.

```
<a href="tel:1930" target="_blank" rel="noopener">1930</a>
<a href="https://cybercrime.gov.in/" target="_blank" rel="noopener
noreferrer">
```

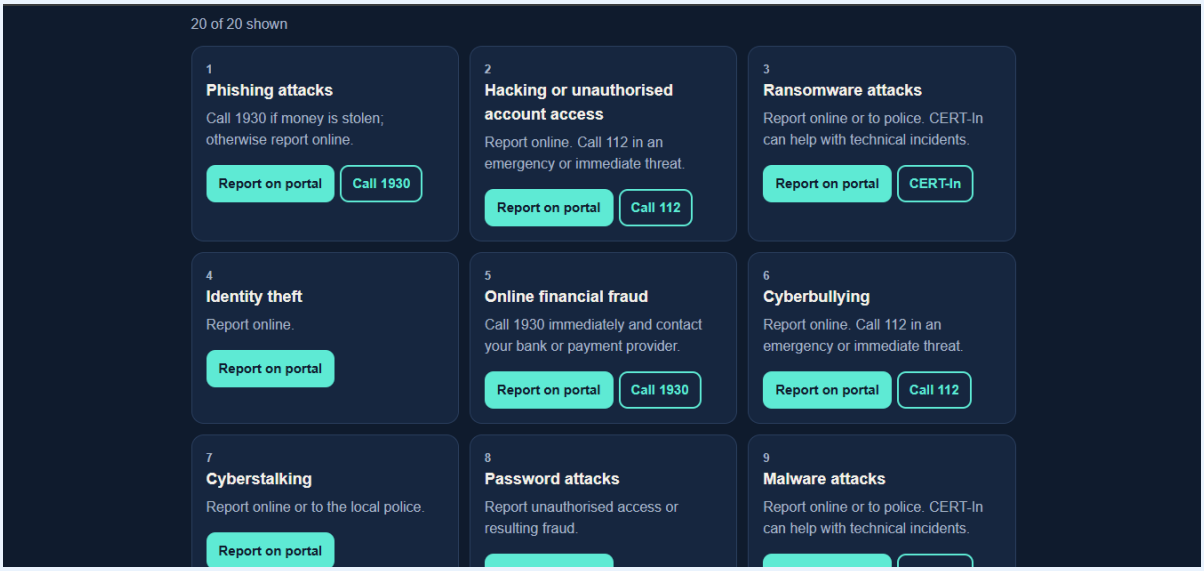

Figure 5: A cybercrime card with the portal and call buttons.

Step 6 — Add multilingual support

I added a language dropdown with English, Hindi and Kannada. All page text, the 20 cybercrime names and the reporting advice are stored per language, and the choice is remembered in the browser. The translations were drafted with AI assistance, so they should be checked by a native speaker.

```
<select id="lang"> English | हिन्दी | ಕನ್ನಡ </select>
apply(): sets every data-k text from the chosen language
```

Figure 6: The website displayed in Hindi and Kannada.

Step 7 — Test locally with VS Code and Live Server

I installed the Live Server extension, trusted the workspace, saved the file as index.html inside the project folder, and clicked Go Live. The site opened at 127.0.0.1:5500. At first the browser showed a directory listing and the extension was disabled; these problems are described in the Challenges section.

```
Extensions > Live Server (Ritwick Dey) > Install
Manage > Trust workspace
Right-click index.html > Open with Live Server
```

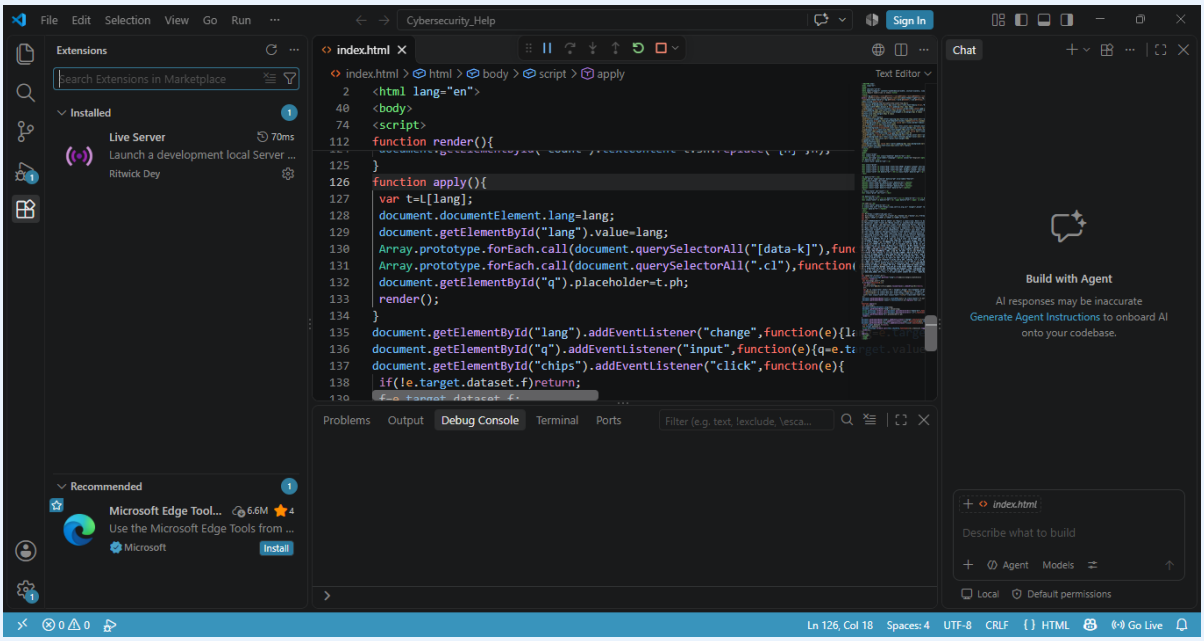

Figure 7: Live Server enabled in VS Code, and the website running at 127.0.0.1:5500.

Step 8 — Test tap-to-call and plan publishing

I tested the call buttons. On a laptop a tel: link cannot place a call, which is expected. When I opened the shared preview link on my phone, the tel: link worked and directed to the phone dail pad .This helps people to directly call when they click on the call button.

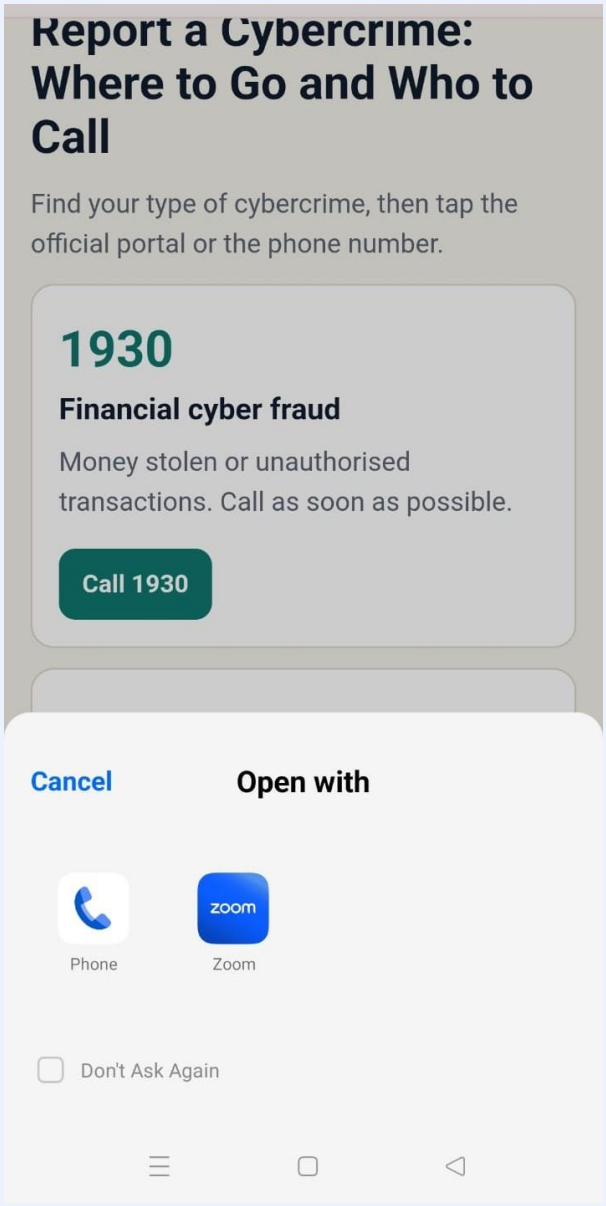

Figure 8: Tap-to-call test on the phone.

5. Results and Observations

5.1 Summary of Findings

#	Finding / Observation	Details	Severity / Impact
1	Directory covers 20 cybercrime types	Each type, from phishing to sextortion, is matched to the official reporting route, with search and filters to find it quickly.	High
2	Emergency numbers reachable in one tap	1930 (financial fraud), 112 (police emergency) and 181 (women's helpline) appear at the top of the page as tap-to-call links.	High
3	Official portal and CERT-In linked directly	Users land on cybercrime.gov.in or cert-in.org.in instead of searching, which reduces the risk of reaching fake reporting sites.	High
4	Three-language interface	English, Hindi and Kannada versions widen access; the translations still need native-speaker review.	Medium
5	Tap-to-call did not open the dial pad from the preview link	A tel: link works on phones but not on laptops, and the shared preview link did not open the dialer on my phone; hosting the file on its own address is the next test.	Medium

5.2 Analysis

The website works because it turns scattered information into one decision: pick the crime type, then follow the shown action. Grouping the crimes by money, threats and technical attacks helps users who do not know the technical name of what happened to them. Linking directly to official sources is important for safety, since scam victims are often targeted again by fake helplines. The tap-to-call issue showed that a feature can behave differently on a laptop, a phone and inside an embedded preview, so testing on the real target device and from the real hosting address is essential. As the site only guides users and does not collect data, it does not store any personal information.

6. Challenges Faced

Challenge Faced	How I Solved It
Live Server was installed but disabled in VS Code.	VS Code was in Restricted Mode. I used Manage > Trust to trust the workspace, after which the extension and the Go Live button worked.
The browser showed “listing directory /” instead of the website.	My file was saved as Cybercrime_Help without the .html extension and no project folder was open. I saved it as index.html inside a project folder, opened that folder in VS Code and clicked Go Live.
The phone numbers did not dial on the laptop, and the dial pad did not open on my phone from the preview link.	I learned that tel: links need a phone and that embedded previews can block them. This is only partly solved: my plan is to host the file on Netlify or GitHub Pages and test again in Chrome, and to add a copy-number fallback.
Keeping 20 cybercrime types in three languages manageable.	I wrote ten reusable action sentences per language and linked each cybercrime type to one of them, instead of writing 20 separate sentences.
Linking to the correct official sites.	I used cybercrime.gov.in and cert-in.org.in, removed a tracking parameter from the original link, and used the main portal because no separate link for the financial fraud portal was provided.

7. Learning Outcomes

- How to structure a responsive single-page website with HTML, CSS and JavaScript.
- How to build search, filter chips and a language switcher by storing data in JavaScript arrays and re-rendering the page.
- How tel: links and external links work, and why they behave differently on laptops, phones and embedded previews.
- How to set up VS Code with the Live Server extension, including workspace trust and the importance of naming the file index.html.
- Which official channels exist in India (cybercrime.gov.in, 1930, 112, 181 and CERT-In) and which cybercrime types should be reported through which route.

SECTION 8 — CONCLUSION & FUTURE SCOPE

8. Conclusion

The project met its objectives: a working, mobile-friendly website that guides a user from the type of cybercrime to the correct official reporting route, with one-tap links to the government portal, three languages and local testing in VS Code. It showed me that cybersecurity includes helping victims respond correctly, not only preventing attacks. The main open issue is confirming that tap-to-call opens the dial pad from a normally hosted address, which I plan to test next.

8.1 Future Scope

Future improvements include hosting the site on Netlify or GitHub Pages with a custom address, adding a copy-number fallback for devices that cannot dial, adding more languages such as Tamil, Bengali and Marathi, having native speakers verify the translations, adding state-wise police cyber cell contacts, and adding a short checklist on what evidence to collect before reporting.

SECTION 9 — REFERENCES

9. References

[1] Government of India — National Cyber Crime Reporting Portal — cybercrime.gov.in

[2] CERT-In, Indian Computer Emergency Response Team — cert-in.org.in

[3] Reference document of reporting websites and contact numbers for 20 types of cybercrime — provided for this project

[4] MDN Web Docs — the tel: URL scheme — developer.mozilla.org

[5] Visual Studio Code documentation — code.visualstudio.com

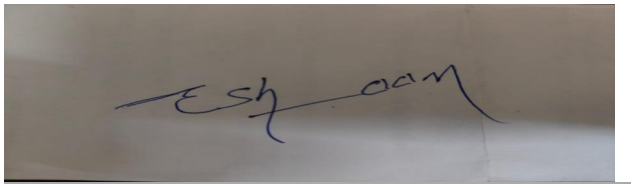

[6] Live Server extension by Ritwick Dey — Visual Studio Marketplace
